# Multidimensional cosmology in Gauss-Bonnet gravity 

Alexey Toporensky

November 30, 2022

We start from the Einstein-Gauss-Bonnet action in $(N+1)$-dimensional spacetime:

$$
S=\frac{1}{16 \pi} \int d^{N+1} \times \sqrt{|\operatorname{det}(g)|}\left(\mathcal{L}_{E}+\alpha \mathcal{L}_{G B}+\mathcal{L}_{m}\right), \quad \mathcal{L}_{E}=R,
$$

$\mathrm{L}_{G B}=R_{\alpha \beta \gamma \delta} R^{\alpha \beta \gamma \delta}-4 R_{\alpha \beta} R^{\alpha \beta}+R^{2},(1)$
where $R, R_{\alpha \beta}, R_{\alpha \beta \gamma \delta}$ are the ( $N+1$ )-dimensional scalar curvature, Ricci tensor and Riemann tensor respectively; $\mathcal{L}_{m}$ is the Lagrangian of a matter; $\operatorname{det}(g)$ is the determinant of a metric tensor $g$. We introduce the metric components as

$$
\begin{equation*}
g_{00}=-1, \quad g_{k k}=\mathrm{e}^{2 H_{k} t}, \quad g_{i j}=0, \quad i \neq j . \tag{2}
\end{equation*}
$$

In the following we interest in the case of $H_{i} \equiv$ const. In this work we deal with a perfect fluid with the equation of state $p=\omega \rho$ as a matter source. Let $\chi=8 \pi \rho$; the equations of motions now can be written as follows:
$2 \sum_{i \neq j} H_{i}^{2}+2 \sum_{\{i>k\} \neq j} H_{i} H_{k}+8 \alpha \sum_{i \neq j} H_{i}^{2} \sum_{\{k>1\} \neq\{i, j\}} H_{k} H_{l}+24 \alpha \sum_{\{i>k>1>m\} \neq j} H_{i} H_{k} H_{l} H_{m}=-\omega x$,

$$
\begin{equation*}
2 \sum_{i>j} H_{i} H_{j}+24 \alpha \sum_{i>j>k>1} H_{i} H_{j} H_{k} H_{l}=x . \tag{3}
\end{equation*}
$$

Since we have $H_{i} \equiv$ const, it follows from Eqs. (3)-(4) that $\rho \equiv$ const, so that the continuity equation

$$
\begin{equation*}
\dot{\rho}+(\rho+p) \sum_{i} H_{i}=0 \tag{5}
\end{equation*}
$$

reduces to

$$
\begin{equation*}
(\rho+p) \sum_{i} H_{i}=0 \tag{6}
\end{equation*}
$$

which allows several different cases: a) $\rho \equiv 0$ (vacuum case), b) $\rho+p=0$ ( $\Lambda$-term case), c) $\sum_{i} H_{i}=0$ (constant volume case) and their combinations: d) $\sum_{i} H_{i}=0$ vacuum and e) $\sum_{i} H_{i}=0$ with $\Lambda$-term. In present paper we do not consider constant volume solutions (CVS), leaving their description for a separate paper. So we left with only options - either vacuum $(\rho=0)$ or $\Lambda$-term $(\rho+p=0)$ and further we consider only these two cases.
Subtracting $i$-th dynamical equation from $j$-th one we obtain:

$$
\begin{equation*}
\left(H_{j}-H_{i}\right)\left(\frac{1}{4 \alpha}+\sum_{\{k>l\} \neq\{i, j\}} H_{k} H_{l}\right) \sum_{k} H_{k}=0 \tag{7}
\end{equation*}
$$

It follows from (7) that

$$
\begin{equation*}
H_{i}=H_{j} \quad \vee \quad \sum_{\{k>1\} \neq\{i, j\}} H_{k} H_{l}=-\frac{1}{4 \alpha} \quad \vee \quad \sum_{k} H_{k}=0 \tag{8}
\end{equation*}
$$

These are necessary conditions for a given set $H_{1}, \ldots, H_{N}$ to be a solution of Eqs. (3)-(4). The case $\sum_{k} H_{k}=0$ is CVS and will be considered in a separate paper; in this section we deal with the following possibilities only:

$$
\begin{equation*}
H_{i}=H_{j} \quad \vee \quad \sum_{\{k>1\} \neq\{i, j\}} H_{k} H_{l}=-\frac{1}{4 \alpha} \tag{9}
\end{equation*}
$$

We call the left equality as type I condition, the right equality as type II condition.
In this case we have 6 pairs of the type I and type II conditions. The table 1 lists all such pairs. We assign numbers from 1 to 6 to each type I condition and letters from $\mathcal{A}$ to $\mathcal{F}$ to each type II condition. There are the following combinations of type I and type II conditions:

1. 0 type I conditions, 6 type II conditions $\Longrightarrow H_{1}=H_{2}=H_{3}=H_{4} \equiv H=\frac{1}{\sqrt{-4 \alpha}}$;
2. 1 (any) type I conditions, 5 type II conditions
$\Longrightarrow H_{1}=H_{2}=H_{3}=H_{4} \equiv H=\frac{1}{\sqrt{-4 \alpha}}$;
3. 2 type I conditions, 4 type II conditions:
3.1 type I conditions has no identical parameters, for example, (see table 1)

$$
1-2-\mathcal{B}-\mathcal{D}-\mathcal{E}-\mathcal{F} \Longrightarrow H_{1}=H_{2} \equiv H, H_{3}=H_{4} \equiv h, H h=-\frac{1}{4 \alpha} ;
$$

3.2 both of type I conditions include one the same parameter, for example,

$$
1-3-\mathcal{C}-\mathcal{D}-\mathcal{E}-\mathcal{F} \Longrightarrow H_{1}=H_{2}=H_{3}=H_{4} \equiv H=\frac{1}{\sqrt{-4 \alpha}} ;
$$

4. 3 type I conditions, 3 type II conditions:
4.1 a chain of conditions does not include one of the parameters, for example,
$1-3-5-\mathcal{C}-\mathcal{D}-\mathcal{F}\left(H_{4}\right.$ is absent $)$
$\Longrightarrow H_{1}=H_{2}=H_{3} \equiv H=\frac{1}{\sqrt{-\alpha}}, H_{4} \equiv h \in \mathbb{R}$,
4.2 a chain of conditions includes all the parameters
$\Longrightarrow H_{1}=H_{2}=H_{3}=H_{4} \equiv H=\frac{1}{\sqrt{-4 \alpha}}$;
5. 4 (or 5) type I conditions, 2 (or 1 ) type II conditions
$\Longrightarrow H_{1}=H_{2}=H_{3}=H_{4} \equiv H=\frac{1}{\sqrt{-4 \alpha}}$;
6. 6 type I conditions, 0 type II conditions $\Longrightarrow H_{1}=H_{2}=H_{3}=H_{4} \equiv H \in \mathbb{R}$.

|  | type I |  | type II |  | type I |  | type II |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $H_{1}=H_{2}$ | $\mathcal{A}$ | $H_{3} H_{4}=-\frac{1}{4 \alpha}$ | 4 | $H_{1}=H_{4}$ | $\mathcal{D}$ | $H_{2} H_{3}=-\frac{1}{4 \alpha}$ |
| 2 | $H_{3}=H_{4}$ | $\mathcal{B}$ | $H_{1} H_{2}=-\frac{1}{4 \alpha}$ | 5 | $H_{2}=H_{3}$ | $\mathcal{E}$ | $H_{1} H_{4}=-\frac{1}{4 \alpha}$ |
| 3 | $H_{1}=H_{3}$ | $\mathcal{C}$ | $H_{2} H_{4}=-\frac{1}{4 \alpha}$ | 6 | $H_{2}=H_{4}$ | $\mathcal{F}$ | $H_{1} H_{3}=-\frac{1}{4 \alpha}$ |

Summarizing aforesaid we see that there are three cases: i)
$H_{1}=H_{2}=H_{3}=H_{4} \equiv H \in \mathbb{R}$ (clearly, $H=\frac{1}{\sqrt{-4 \alpha}}$ is the subcase of that case); ii)
$H_{1}=H_{2}=H_{3} \equiv H=\frac{1}{\sqrt{-4 \alpha}}, H_{4} \equiv h \in \mathbb{R}$; iii) $H_{1}=H_{2} \equiv H$,
$H_{3}=H_{4} \equiv h, H h=-\frac{1}{4 \alpha}$.
In the ( $5+1$ ) dimensional case we have 10 pairs of the type I and type II conditions (9). Note that, as distinct from the (4+1)-dimensional case, type II conditions are the sums of three pairwise products of Hubble parameters but it does not affect follow-up reasoning: as in the (4+1)-dimensional case one can check that there are the following necessary conditions for a given set of the Hubble parameters $H_{1}, \ldots, H_{5}$ to be a solution of the dynamical equations: i)
$H_{1}=H_{2}=H_{3}=H_{4}=H_{5} \equiv H$; ii) $H_{1}=H_{2}=H_{3}=H_{4} \equiv H, H_{5} \equiv h$; iii)
$H_{1}=H_{2}=-H_{3}=-H_{4} \equiv H, H_{5} \equiv h$; iv) $H_{1}=H_{2}=H_{3} \equiv H, H_{4}=H_{5} \equiv h$.
Explicit form of these solutions have been written down in
Dmitry Chirkov, Sergey Pavluchenko, Alexey Toporensky, Exact exponential solutions in Einstein-Gauss-Bonnet flat anisotropic cosmology, Mod. Phys. Lett. A 29, 1450093 (2014).

The same procedure works also for higher order Lovelock gravity, see
Dmitry Chirkov, Sergey Pavluchenko, Alexey Toporensky, Non-constant volume exponential solutions in higher-dimensional Lovelock cosmologies, General Relativity and Gravitation 47, 137 (2015).
The question arises: can we consider exponential solution as a typical outcome of cosmological evolution which starts from totally anisotropic initial conditions? The answer is "Yes". See
Dmitry Chirkov, Alexey Toporensky, Splitting into two isotropic subspaces as a result of cosmological evolution in Einstein-Gauss-Bonnet gravity, Grav. Cosmol. Vol. 25, No. 3, p. 243 (2019)
From Conclusions of this paper:
We have considered a cosmological evolution of a flat $5+1$ and $6+1$ dimensional anisotropic Universe in Gauss-Bonnet gravity. We started from an arbitrary anisotropic initial conditions and study the outcome of corresponding cosmological evolution. Three possible outcomes have been identified. About a half of trajectories traced (we have about $10^{4}$ trajectories for each dimensionality) ends in a non-standard singularity. A few percents of trajectories represent a periodic in Hubble parameters solution. And the rest of them (roughly a half of overall number) lead to exponential solutions. Our results show that a situation when a space is splitted into a warped product of isotropic subspaces can be a natural result in cosmological evolution of a flat Universe in Gauss-Bonnet gravity.

It is shown that spatial curvature in the "inner" subspace can stabilize the size of extra dimensions.
Dmitry Chirkov, Alex Giacomini, Sergey A. Pavluchenko, Alexey Toporensky, Cosmological solutions in Einstein-Gauss-Bonnet gravity with static curved extra dimensions, arXiv:2012.03517
These results allow us to construct a scenario of compactification which satisfy two important requirements:

- the evolution starts from a rather general anisotropic initial conditions,
- the evolution ends in a state with three isotropic big expanding dimensions and stabilized isotropic extra dimensions.

This scenario consists from two steps.

1. An anisotropic flat Universe evolves to a product of two isotropic spaces.
2. Contracting subspace stabilizes due to spatial curvature.
