Determination of the radii of states in the 11-14 MeV excitation region in the ^9Be nucleus

Tuesday, 29 November 2022 17:10 (120)

The angular distributions for the 11.28 ($7/2^+$), 11.82 ($9/2^-$), and 13.79 ($7/2^-$) MeV states were obtained and analyzed from the scattering of light particles by the ^9Be nucleus.[1,2]. The MDM method was used to estimate the radii [3]. The resulting diffraction radius of the 11.82 MeV state turned out to be equal to the radius of the ground state. This indicates that the root-mean-square radius of this state is ordinary. For the 11.28 MeV and 13.79 MeV states, the diffraction radii turned out to be increased, which indicates increased root-mean-square radii for these states. On the basis of the obtained radii and certain spin-parity values (rule $J(J+1)$ [4]) of the states 11.82, 11.28, and 13.79, it was possible to assign them to the first, second, and third bands of the ^9Be nucleus, respectively.
