

Inclusive $Z(\nu\bar{\nu})\gamma$ full Run2 analysis report

Diana Pyatiizbyantseva
on behalf of the ZnunuGamma group

National Research Nuclear University “MEPhI”

MEPhI@Atlas meeting

July 08, 2022

Motivation

➤ Standard Model:

- A higher branching ratio of the neutral decay channel in comparison to the charged lepton decays of Z boson and better background control in comparison with the hadronic channel.

- [Previous study](#) for this channel — 36.1 fb^{-1} data.

Full Run2 statistics (139 fb^{-1}) → increase of measurement accuracy (expectation of an increase in the experimental sensitivity by a factor of 2).

- Goal: integral and differential in \mathbf{E}_T^γ , \mathbf{N}_{jets} , $\mathbf{p}_T^{\text{miss}}$, $\Delta\phi[\gamma, \mathbf{p}_T^{\text{miss}}]$, $\mathbf{p}_T(\mathbf{Z}\gamma)$, η_γ cross-sections. Comparison with theory predictions including NNLO QCD and [NLO EWK corrections](#).

➤ Beyond SM:

- The strongest up-to-date limits on anomalous neutral triple gauge-boson couplings (aTGCs) using vertex functions and EFT formalisms → **interpretation**.

➤ **Combination** of the EFT limits between $Z\gamma$ and ZZ + ratio of $Z\gamma/ZZ$ cross-sections.

Glance: [ANA-STDM-2018-54](#)

Selection optimisation: increase in statistical significance

Topology: high-energetic γ + high missing transverse momentum p_T^{miss}

Multivariate (MV) method of the selection optimisation takes into account the signal significance Z as a function of the threshold values of the variables:

$$Z = N_{\text{signal}} / \sqrt{N_{\text{signal}} + N_{\text{bkg}}}$$

The output of the MV optimisation procedure is a vector of threshold values of the variables at which the maximum Z is reached.

Uncomplicated method (unlike TMVA) is useful for differential cross-section measurements.

Preselections	Cut Value
E_T^{miss}	> 120 GeV
E_T^γ	> 150 GeV
Number of tight isolated photons	$N_\gamma = 1$
Lepton veto	$N_e = 0, N_\mu = 0$
Selections	Cut Value
E_T^{miss}	> 130 GeV
SR E_T^{miss} significance	> 11
$ \Delta\phi(\vec{p}_T^{\text{miss}}, \gamma) $	> 0.6
$ \Delta\phi(\vec{p}_T^{\text{miss}}, j_1) $	> 0.4

Selections	N_{signal}	$N_{\text{bkg}}, \cdot 10^3$	Z
Preselections	12380 ± 9	77.6 ± 0.7	41.3 ± 0.2
Selections	9843 ± 8	15.5 ± 0.5	61.8 ± 0.6
- $E_T^{\text{miss}} > 130$ GeV	9939 ± 8	16.2 ± 0.5	61.5 ± 0.6
- E_T^{miss} significance > 11	11261 ± 8	33.1 ± 0.6	53.5 ± 0.3
- $ \Delta\phi(\vec{p}_T^{\text{miss}}, \gamma) > 0.6$	9858 ± 8	16.0 ± 0.5	61.4 ± 0.6
- $ \Delta\phi(\vec{p}_T^{\text{miss}}, j_1) > 0.4$	10016 ± 8	17.6 ± 0.5	60.3 ± 0.6

No significant increase in statistical significance with using $N_{\text{b-jets}}$ and p_T^{SoftTerm} variables.

Photon pointing: beam-induced background (BIB)

- Muons from pion and kaon decays in hadronic showers, induced by beam losses in non-elastic collisions with gas and detector material, deposit large amount of energy in calorimeters through radiative processes (= **fake jets**).
- The characteristic peaks of the fake jets due to BIB concentrate at $\pm \pi$ and $\mathbf{0}$ (mainly due to the bending in the horizontal plane that occurs in the D1 and D2 dipoles and the LHC arc).

Cuts: $|\phi| < 0.2$, $|\phi| \in [2.9; 3.2]$ and $|\eta| > 1.7$

$|\Delta z| < 250 \text{ mm}$

Rejection efficiency: $(100 \pm 3)\%$
 Acceptance efficiency: $(99.7 \pm 0.9)\%$

Background composition

Percentage of
the total
predicted
background

Background composition for $Z(\nu\nu)\gamma$:

- 35 % ● γ +jets – via MC → ABCD method based on E_T^{miss} -significance and additional variable
- 27 % ● $W(l\nu)\gamma$ – fit to data in additional CR based on N_{lep} (shape from MC)
- 21 % ● $e\rightarrow\gamma$ – fake-rate estimation using Z-peak (tag-n-probe) method
- 14 % ● $\text{jet}\rightarrow\gamma$ – ABCD method based on γ ID and isolation
- 1.9 % ● $Z(l^+l^+)\gamma$ – via MC
- 1.5 % ● $t\bar{t}\gamma$ – via MC

jet \rightarrow γ misID background: correlation factor

Background is estimated from data using **2D-sideband method**:

Photon isolation and identification variables are used to construct the sidebands.

Correlation is measured in data and MC by $R = \frac{N_A N_D}{N_B N_C}$.

Non-tight: at least one of the cuts on the following variables should fail in these:

- loose'2: w_{s3}, F_{side}
- loose'3: $w_{s3}, F_{side}, \Delta E$
- loose'4: $w_{s3}, F_{side}, \Delta E, E_{ratio}$
- loose'5: $w_{s3}, F_{side}, \Delta E, E_{ratio}, w_{tot}$

FixedCutTightCaloOnly:

A: tight, $E_T^{cone40} - 0.022 p_T^Y < 2.45$ [GeV]

B: tight, $2.45 + \text{gap} < E_T^{cone40} - 0.022 p_T^Y$ [GeV]

C: non-tight, $E_T^{cone40} - 0.022 p_T^Y < 2.45$ [GeV]

D: non-tight, $2.45 + \text{gap} < E_T^{cone40} - 0.022 p_T^Y$ [GeV]

Isolation should not correlate with non-tight ID!

$$\frac{N_A^{jet \rightarrow \gamma}}{N_B} = \frac{N_C}{N_D}$$

Isolated Non-isolated

Isolated Non-isolated

jet $\rightarrow \gamma$ misID background: uncertainties

➤ Statistical uncertainty:

- The event yields of four regions in data and non jet $\rightarrow \gamma$ background are varied by $\pm 1\sigma$ independently (**4%**).
- The statistical uncertainty on the signal leakage parameters is negligible.

Total statistics: 4%.

Central value	1960 \pm 83
loose'3	-334
loose'4	-397
loose'5	-472
Isolation gap +0.15 GeV	+33
Isolation gap -0.15 GeV	-22

➤ Systematic uncertainty:

- Anti-tight definition and isolation gap choice – variations of ABCD regions determination for $\pm 1\sigma$ changes in data yield (**24%**).
- Uncertainty coming from the signal leakage parameters is obtained via using different generators and parton shower models (**9%**).

Signal leakage parameters	MadGraph+Pythia8, Sherpa 2.2	MadGraph+Herwig7, MadGraph+Pythia8	Relative deviation
c_B	0.0713 \pm 0.0002	0.1000 \pm 0.0011	29%
c_C	0.00879 \pm 0.00007	0.0092 \pm 0.0003	4%
c_D	0.00070 \pm 0.00002	0.00099 \pm 0.00010	29%
$jet \rightarrow \gamma$ est.	1960	1785	9%

- The iso/ID uncertainty on reconstruction photon efficiency $\delta_{\text{eff}}^{\text{iso/ID}}$ (**1.4%**):

$$\sigma_{\text{iso}}^{\text{CB}}(\text{relative}) = \delta_{\text{iso}}^{\text{eff}} * (c_B + 1)/c_B$$

$$\sigma_{\text{ID}}^{\text{CC}}(\text{relative}) = \delta_{\text{ID}}^{\text{eff}} * (c_C + 1)/c_C$$

$$\sigma_{\text{iso}}^{\text{CD}}(\text{relative}) = \delta_{\text{iso}}^{\text{eff}} * (c_B + 1)/c_B$$

$$\sigma_{\text{ID}}^{\text{CD}}(\text{relative}) = \delta_{\text{ID}}^{\text{eff}} * (c_C + 1)/c_C$$

$$\delta_{\text{iso}}^{\text{eff}} = 0.013$$

$$\delta_{\text{iso/ID}}^{\text{eff}} = 0.013$$

Total systematics: 26%.

★ **Total number of jet $\rightarrow \gamma$ events:** 1960 \pm 80 \pm 510. Z(vv)+jets and multi-jet MC predicts 1600 \pm 1200 events.

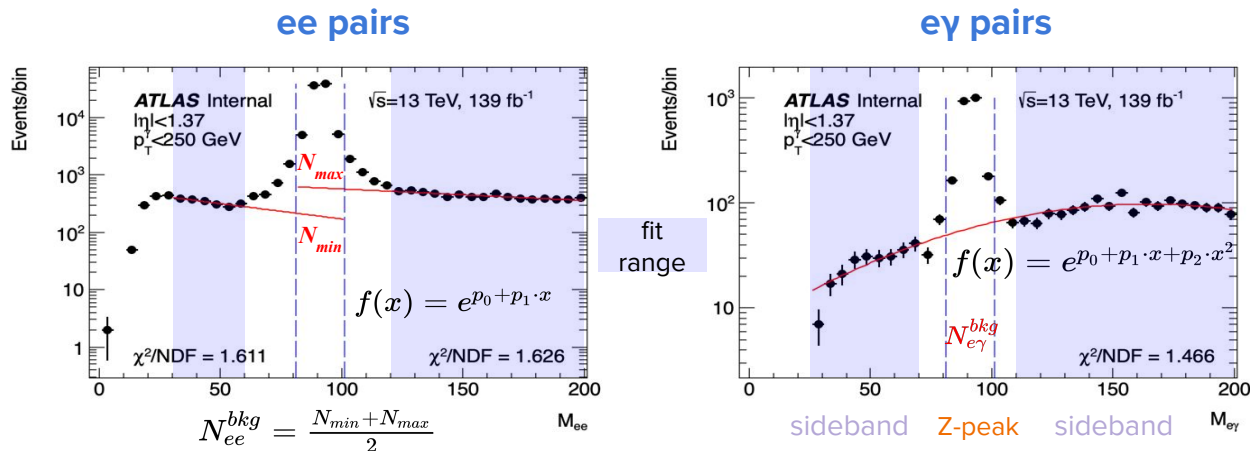

$e \rightarrow \gamma$ misID background: Z-peak method

Source: W(lv), top and tt processes.

Estimation procedure:

1. estimating $e \rightarrow \gamma$ fake rate as $rate_{e \rightarrow \gamma} = \frac{(N_{e\gamma} - N_{bkg})}{(N_{ee} - N_{bkg})}$,

where N_{ee} , $N_{e\gamma}$ – number of ee and eγ events in Z-peak mass window ($M_Z - 10$ GeV, $M_Z + 10$ GeV), N_{bkg} – background in Z-peak mass window extrapolated from sideband with exponential pol1 or pol2 fit.

2. building e-probe CR (SR with electron instead of photon).

3. scaling data distributions from e-probe CR on fake rate.

$e \rightarrow \gamma$ misID background: uncertainties

Since $e \rightarrow \gamma$ fake rate depends on η и p_T , it is estimated in three regions.

Systematics:

1. Fake-rate:

- Z-peak mass window variation (varies from 0.5% to 0.9%).
- Background under Z-peak evaluation (varies from 2.2% to 10.4%).
- Difference between "real fake rate" in Z(ee) MC and tag-and-probe method performed on Z(ee) MC (varies from 1.13% to 19.4%).

Total systematics on the fake-rate: 22%.

2. E-probe CR:

- Impurity of the region (0.46%).

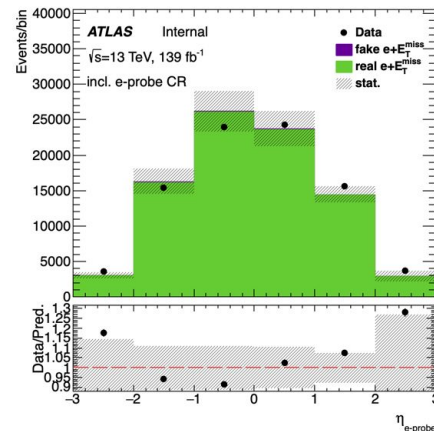

Total syst. on the background yield: 6%.

Total background (e-probe region scaled by fake-rate): $3070 \pm 12 \pm 187$.

$e \rightarrow \gamma$ fake rates		
	$150 < E_T^\gamma < 250$ GeV	$E_T^\gamma > 250$ GeV
$0 < \eta < 1.37$	$0.0240 \pm 0.0006 \pm 0.0009$	$0.0205 \pm 0.0013 \pm 0.0045$
$1.52 < \eta < 2.37$	$0.0696 \pm 0.0018 \pm 0.0072$	

Contamination is determined as:

$$\frac{\text{fake } e + E_T^{\text{miss}}}{\text{real } e + E_T^{\text{miss}}}$$

jet \rightarrow E_T^{miss} misID background: estimation strategy

- Background originating from γ +jets processes is significantly reduced by applying selections on E_T^{miss} and E_T^{miss} -**significance**.
- For now, **MC simulation** is used to estimate this background.
- The MC normalisation is estimated from the CR constructed in **low- E_T^{miss} -significance range** (E_T^{miss} -significance < 11) with E_T^{miss} **selection relaxed** to $E_T^{\text{miss}} > 100$ GeV.
- Normalisation coefficient is equal to **0.66**, which is close to the normalisation factor obtained using 2D-sideband method in $Z(\nu\nu)\gamma$ EWK analysis (0.68).
- The plan is to estimate this background for each bin using **2D-sideband method**: E_T^{miss} -significance and other discriminative variable (e.g. $\Delta\phi[\gamma, p_T^{\text{miss}}]$ or p_T^{SoftTerm}) will be used to construct the sidebands.

Control plots

For $\text{jet}\rightarrow\gamma$ bkg, the shape is taken from $Z(\nu\nu)\gamma$ QCD MC. $\gamma+\text{jet}$ bkg has 0.66 normalisation. $e\rightarrow\gamma$ bkg: DD.

The total uncertainty includes the statistical uncertainty for all bkg, while for $\text{jet}\rightarrow\gamma$ and $e\rightarrow\gamma$ bkg there is also the systematic uncertainty.

Control plots

For $\text{jet}\rightarrow\gamma$ bkg, the shape is taken from $Z(\nu\nu)\gamma$ QCD MC. $\gamma\text{+jet}$ bkg has 0.66 normalisation. $e\rightarrow\gamma$ bkg: DD.

The total uncertainty includes the statistical uncertainty for all bkg, while for $\text{jet}\rightarrow\gamma$ and $e\rightarrow\gamma$ bkg there is also the systematic uncertainty.

Summary

- Several steps of the inclusive $Z(\nu\bar{\nu})\gamma$ Run2 analysis are already done: selection optimisation, data-driven estimation of $\text{jet}\rightarrow\gamma$, $e\rightarrow\gamma$ and (preliminary) $E_T^{\text{miss}}\rightarrow\text{jet}$ misID backgrounds, control plots.
- Plans:
 - Re-optimize the SR after adding $Z(\nu\bar{\nu})\gamma$ and $W\gamma$ EWK samples + $W(\tau\nu)$ samples with separation of lepton and hadron channels.
 - Estimate:
 - $E_T^{\text{miss}}\rightarrow\text{jet}$ background using 2D-sideband method.
 - pile-up background (expected to be negligible).
 - $W\gamma$ background.
 - Uncertainties.
 - Cross-section measurements.
 - Limits on aTGCs.
 - EB request till the end of the year.

Back-up

Object selections

Photon selection:

$E_T^\gamma > 10$ GeV, $|\eta| < 2.37$, crack region excluded, cluster quality cut, ambiguity cut, tight ID, FixedCutTightCaloOnly isolation, $\Delta R(\gamma, e/\mu) < 0.4$

Electron selection:

$p_T > 4.5$ GeV, $|\eta| < 2.47$, crack region excluded, loose ID, $\Delta R(e, \mu) < 0.1$

Muon selection:

$p_T > 4$ GeV, $|\eta| < 2.47$, crack region excluded, loose ID, $l_{z_0} \cdot \sin\theta_l < 0.5$ mm, d_0 signif. < 3

Jet selection:

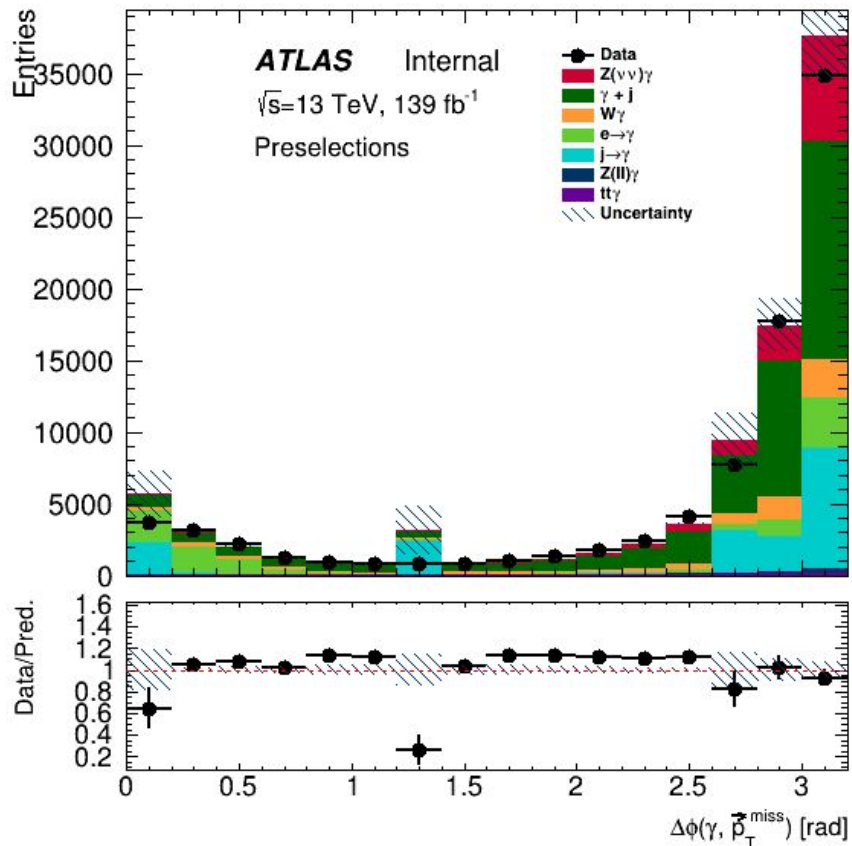

$E_T > 50$ GeV, $|\eta| < 4.5$, AntiKt4EMPFJet, tight JVT, $\Delta R(\text{jet}, e/\mu/\gamma) < 0.4$

Selection optimisation: distributions

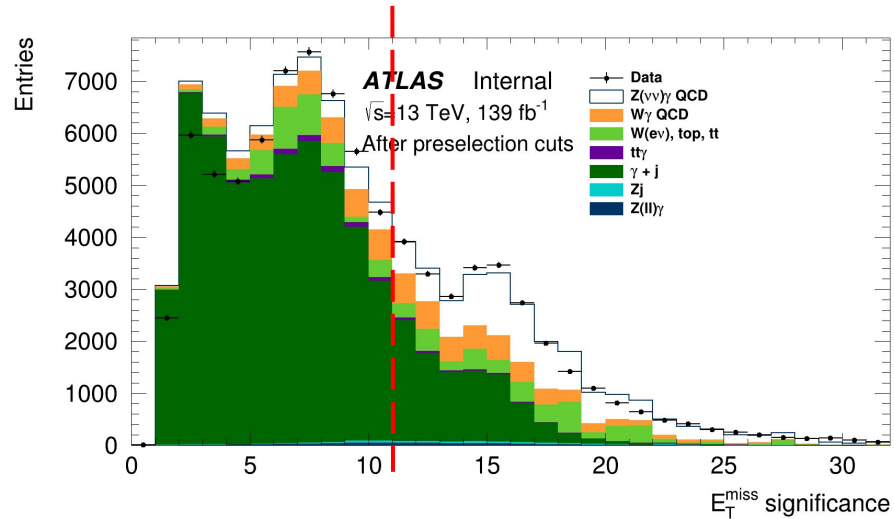

For jet $\rightarrow\gamma$ bkg, the shape is taken from $Z(\nu\nu)$ +jets and multi-jet MC. γ +jet bkg has 0.66 normalisation. $e\rightarrow\gamma$ bkg: $W(\text{ev})$, $W(\text{rv})$, top, tt MC.

Selection optimisation: distributions

For jet $\rightarrow\gamma$ bkg, the shape is taken from $Z(\nu\nu)$ +jets and multi-jet MC. γ +jet bkg has 0.66 normalisation. $e\rightarrow\gamma$ bkg: $W(e\nu)$, $W(\nu\nu)$, top, $t\bar{t}$ MC.

Selection optimisation: multi-jet problematic normalisation

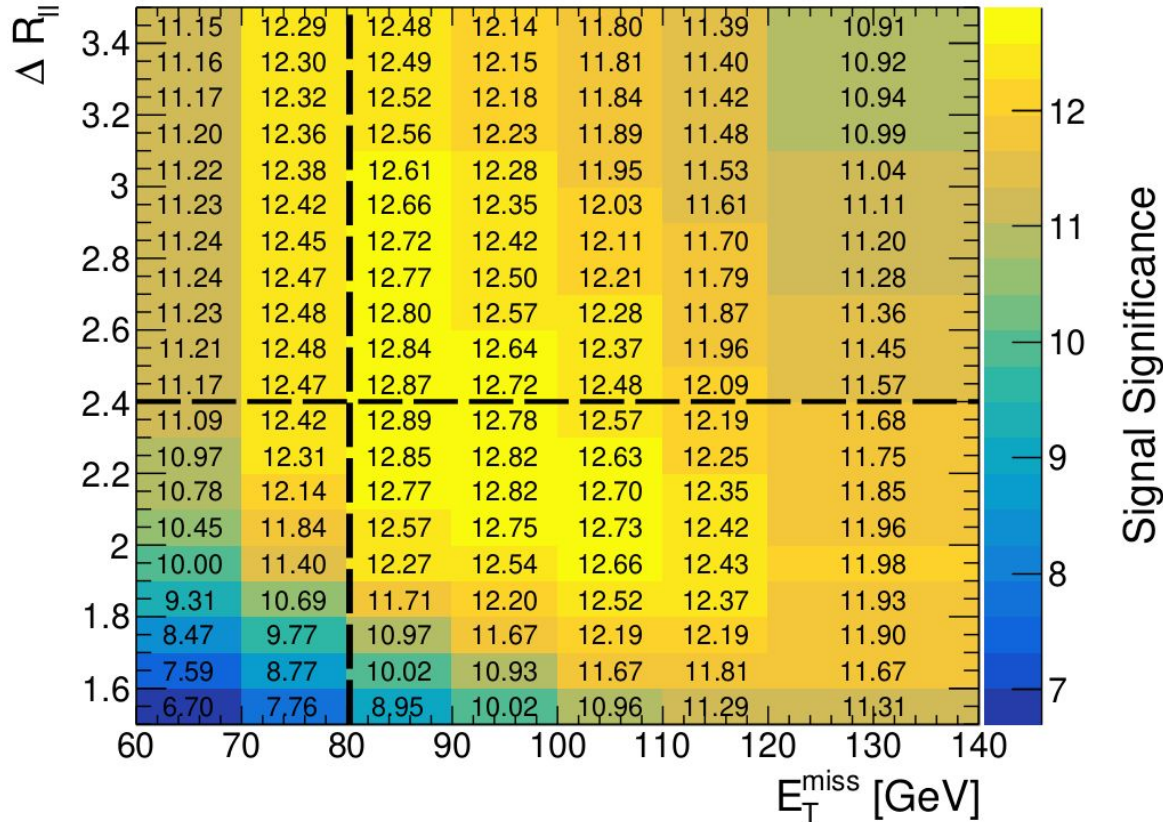

without multi-jet samples

with multi-jet samples

Multi-jet samples are not used for the optimisation procedure due to their problematic normalisation.

Multivariate method of optimisation (2D example)

Selection optimisation: $N_{b\text{-jet}}$ and p_T^{SoftTerm}

Selection optimisation: event yields

$$\Delta\left(\frac{x}{y}\right) = \sqrt{\left(\frac{\Delta x}{y}\right)^2 + \left(\frac{x \Delta y}{y^2}\right)^2}$$

jet \rightarrow γ misID background: estimation technique

The signal leakage parameters:

$$c_i = \frac{N_i^{\text{sig}}}{N_A^{\text{sig}}}$$

MC \rightarrow

$$\tilde{N}_i = N_i - N_i^{\text{bkg}}$$

$$N_A^{\text{sig}} = \tilde{N}_A - R(\tilde{N}_B - c_B N_A^{\text{sig}}) \frac{\tilde{N}_C - c_C N_A^{\text{sig}}}{\tilde{N}_D - c_D N_A^{\text{sig}}}$$

The number of events arising in each of the regions:

$$N_A = N_A^{\text{sig}} + N_A^{\text{bkg}} + N_A^{\text{jet} \rightarrow \gamma};$$

$$N_B = c_B N_A^{\text{sig}} + N_B^{\text{bkg}} + N_B^{\text{jet} \rightarrow \gamma};$$

$$N_C = c_C N_A^{\text{sig}} + N_C^{\text{bkg}} + N_C^{\text{jet} \rightarrow \gamma};$$

$$N_D = c_D N_A^{\text{sig}} + N_D^{\text{bkg}} + N_D^{\text{jet} \rightarrow \gamma};$$

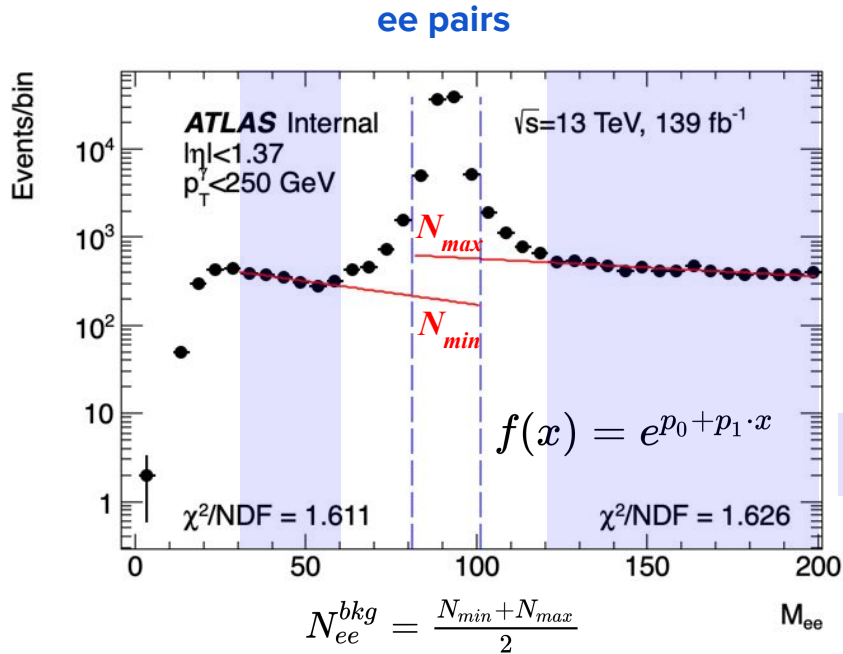

$$N_A^{\text{sig}} = \frac{b - \sqrt{b^2 - 4ac}}{2a}$$

$$\begin{cases} a = c_D - R c_B c_C; \\ b = \tilde{N}_D + c_D \tilde{N}_A - R(c_B \tilde{N}_C + c_C \tilde{N}_B); \\ c = \tilde{N}_D \tilde{N}_A - R \tilde{N}_C \tilde{N}_B. \end{cases}$$

$$N_A^{\text{jet} \rightarrow \gamma}$$

$e \rightarrow \gamma$ misID background: background under Z peak

- Systematics on bkg estimation under Z peak are evaluated by variation of N^{bkg} values in ee and ey pairs.
- N_{min} and N_{max} values are used as variations of N_{ee}^{bkg} . In ey pairs extrapolation function parameters are varied by their statistical uncertainties one by one. Resulting integral of the function is used for variation of N_{ey}^{bkg} .
- Sum in quadrature of the largest variations of N_{ey}^{bkg} and N_{ee}^{bkg} is taken as systematics.

$E_T^{\text{miss}} \rightarrow$ jet misID background: estimation strategy

var1	$E_T^{\text{miss}} \text{ signif} > 11$	1.3101
var2	$p_T^{\text{SoftTerm}} < 16$	
var1	$E_T^{\text{miss}} \text{ signif} > 11 \ \&\& \ \Delta\phi(\text{jet_lead}, p_T^{\text{miss}}) > 0.4$	1.24685
var2	$p_T^{\text{SoftTerm}} < 16$	
var1	$E_T^{\text{miss}} \text{ signif} > 11 \ \&\& \ \Delta\phi(\text{jet_lead}, p_T^{\text{miss}}) > 0.4 \ \&\& \ \Delta\phi(\gamma, p_T^{\text{miss}}) > 0.6$	1.24627
var2	$p_T^{\text{SoftTerm}} < 16$	

R for variables configurations w/o soft term is very bad ($\gg 1$)

Pile-up background

- In full Run2 Z($\ell\gamma$) inclusive analysis it was found that events with Z and photon from different primary vertices have non-negligible probability (up to **5%** of the total event yield)
- Since our final state assumes high energetic photons, E_T^{miss} , probability of such events should be much smaller.
- Fraction of pile-up background is calculated as:

$$f_{\text{PU}} = \frac{N_{\text{data}, 2\text{-track Si}}^{|\Delta z| > 50\text{mm}} - N_{\text{single pp}, 2\text{-track Si}}^{|\Delta z| > 50\text{mm}}}{N_{\text{data}, 2\text{-track Si}} \times 0.32}, \quad N_{\text{single pp}, 2\text{-track Si}}^{|\Delta z| > 50\text{mm}} = SF_1 \times SF_2 \times N_{\text{MC}, 2\text{-track Si}}^{|\Delta z| > 50\text{mm}}$$

- SF_1 is equal to the ratio of events in data to events in Sherpa MC sample near $|\Delta z|$ around zero (4.61 ± 0.07)
- SF_2 – normalization factor taking into account the mismodelling in the tails of $|\Delta z|$ distribution (it was calculated for Sherpa Z γ QCD by Z($\ell\gamma$) inclusive team using events with FSR photons) (1.5 ± 0.3)

$$f_{\text{PU}} = -(58 \pm 11)\%$$
