Abstract

We deduce the $D$ meson and nucleon interactions from the QCD sum rules. Unifying the chiral SU(3) model, we study the in-medium mass splitting between pseudoscalar $D^+$ and $D^-$ meson in the hot and dense asymmetric nuclear matter. The medium modified quark and gluon condensates are evaluated from the chiral SU(3) model and further plugged into the QCD sum rules to compute the in-medium mass of pseudoscalar $D$ meson. We find that the mass of both $D^+$ and $D^-$ meson increase with the medium density. The calculated $D$ meson mass in central approximation and compared it with the mass of $D^+$ and $D^-$ meson. By plugging the in-medium mass of $D^+$ and $D^-$ meson in the mass splitting formula, $\Delta m^{\pi}(m_{D^+}^2 - m_{D^-}^2)$, we observe non-negligible splitting in the $D^+$ and $D^-$ mass which increases appreciably as a function of nuclear density. The medium modified mass evaluated in this work can be used as application to study the decay width of higher charmonia states decaying into $D^+D^-$ pairs.

Introduction

In-medium effects of pseudoscalar $D$ meson can be used to study the $J/\psi$ suppression [1, 2]. Various theoretical studies have been done to study the in-medium properties of pseudoscalar $D$ mesons. For example, the in-medium mass and decay constant of $D$ meson was studied using the method of Borel transformation [1, 2, 3, 4] and Operator Product Expansion [1, 2]. In addition to the density, temperature, and asymmetry of the medium, recently in heavy-ion collisions, the effect of the strong magnetic field was also found [2, 3, 5]. Therefore, the study of hadrons under magnetic effects attracts the interest of many researchers [2, 3, 5]. In this article, the scalar and vector densities with and without the effect of the magnetic field are calculated using the chiral SU(3) model and these medium effects are relayed by scalar fields to the quark and gluon condensates [2]. These condensates are further coupled with even-odd sum rules to evaluate the $D$ meson mass.

Methodology

- The Chiral SU(3) Model

In the model, the density dependent light quarks $\langle \bar{q}q \rangle$ and scalar gluon condensate $\langle \frac{1}{2} G^2 \rangle$ can be written as [2, 6]

$$\langle \bar{q}q \rangle = \frac{1}{m_q} \left\{ \frac{1}{4} \left( \frac{1}{2} m_q^2 f_{\pi} \right)^2 (\sigma - \delta) \right\}$$

and

$$\langle \frac{1}{2} G^2 \rangle \equiv \frac{4}{9} \left\{ (1 - \xi) \lambda^2 + \left( \frac{1}{4} \right)^2 \left( m^2 f_{\pi} \sigma \right) \right\} + \sqrt{2} m_f f_{\pi} \left\{ \frac{1}{2} m_f f_{\pi} \zeta \right\}$$

- Even-odd QCD Sum Rules

In this section, we derive the expression for the in-medium mass of $D^+(c\bar{s})$ and $D^+(d\bar{s})$ mesons. In QCD Sum Rules, the in-medium properties of mesons are studied using the two-point current correlation function, given by

$$\Pi(q) = i \int d^4 x e^{i q \cdot x} \langle 0 \mid T \left[ \langle 0 | \left( \chi_{\pi}^s(0) \right) \Pi(\xi) \right] | 0 \rangle \rangle \quad \text{(3)}$$

The current correlation function, $\Pi(q_0, q^i)$ can be expressed into an even and odd part as

$$\Pi(q_0, q^i) = \Pi^e(q_0, q^i) + q_0 \Pi^o(q_0, q^i).$$

Using Borel transformation, the in-medium mass of the $D^+(m_{D^+}^2)$ and $D^-(m_{D^-}^2)$ can be written as [4, 3]

$$w_0 = \left\{ \frac{1}{2} q^2 (M, m_{D^+}^2) \right\}^2 \left\{ \frac{1}{2} q^2 (M, m_{D^-}^2) \right\}^2 \left\{ \frac{1}{2} q^2 (M, m_{D^+}^2) \right\}^2 \left\{ \frac{1}{2} q^2 (M, m_{D^-}^2) \right\}^2$$

In the presence of the magnetic field, due to Landau quantization effect, the in-medium mass of charged $D$ meson modify as [2]

$$m_{D^+}^2 = m_{D^+}^2 + c B$$

where $c B$ is the magnetic field. The mass-splitting with $(*)$ and without $(*)$ magnetic field effect can be written as

$$\Delta m^{**} = m^{**} - m^{*}.$$
