On stability of exponential cosmological solutions with non-static volume factor in the Einstein-Gauss-Bonnet model

Tuesday, 11 October 2016 16:45 (15)

A (n+1)-dimensional gravitational model with Gauss-Bonnet term and cosmological constant term is considered. When ansatz with diagonal cosmological metrics is adopted, the solutions with exponential dependence of scale factors: $a_i \sim \exp(v^i t)$, i = 1, ..., n, are considered. We study the stability of the solutions with non-static volume factor, i.e. if $K(v) = \sum_{k=1}^n v^k \neq 0$. We prove that under certain restriction R imposed solutions with K(v) > 0 are stable while solutions with K(v) < 0 are unstable. Certain examples of stable solutions are presented. We show that the solutions with $v^1 = v^2 = v^3 = H > 0$ and zero variation of the effective gravitational constant are stable if the restriction R is obeyed.
