## The 7th international conference on particle physics and astrophysics

Contribution ID : 173 Type : Oral talk

## First measurements of 239Pu fission fraction and long term reactor power monitoring using antineutrino spectrum

Wednesday, 23 October 2024 11:15 (15)

The highly segmented DANSS anti-neutrino scintillation detector is located at the Kalinin NPP and collects up to 5000 antineutrino events per day. The reactor power was measured using the inverse beta-decay (IBD) event rate during 7.5 years with an accuracy of 1.3% in 3 days and with the relative systematic uncertainty of less than 0.8%. The report will present the measured dependence of the antineutrino spectrum on the composition of reactor fuel. The measured ratio of cross-sections 235U/239Pu will be presented. The 239Pu fission fraction was measured during 7 years of the reactor operation using a fit of the measured IBD positron spectrum with model predictions for different isotopes. Taking into account the absolute antineutrino counting rates, the parameters of a hypothetical sterile neutrino region was extended above  $\Delta m^2 > 5$  eV<sup>2</sup>, where there are indications of the existence of a sterile neutrino in the BEST and Neutrino-4 experiments
