Open and hidden strangeness in central A+A collisions from SPS to LHC: ratios of transverse energy density at midrapidity for the identified hadrons with different strangeness content

Thursday, 24 October 2024 11:15 (15)

We continue studies of the effects previously observed in very central (0-5% class) relativistic heavy-ion collisions where we found that the ratios of the Bjorken energy density fractions, relevant to the identified hadrons, practically are not depending on the collision energy in all cases of open and hidden strangeness [1]. In our new work, we include into the analysis the additional HEP data on the yields of particles containing one, two or three strange quarks. This includes Λ baryon and K^0_S meson, Ξ and Ω hyperons yields measured in Au-Au and Pb-Pb collisions at $\sqrt{s_{NN}} = 39$ GeV, 200 GeV and 2.76 TeV. The particle HEP data spectra were approximated in each case by the Levy functions, and in such way the relevant mean p_t was obtained and used in the calculations of the mean transverse energy density at midrapidity for the particle (i) of interest. The Blast Wave approximation for the spectra shape was also used to compare and to estimate the systematic error of mean p_t and of the relevant mean $\langle dE_t/dy \rangle_i$. Finally, the ratios were obtained of mean $\langle dE_t/dy \rangle_\phi / \langle dE_t/dy \rangle_i$ – for ϕ -mesons and other particles, registered at midrapidity in central A+A collisions. The results are discussed. The authors acknowledge Saint-Petersburg State University for a research project 95413904. References: [1] O. Shaposhnikova, A. Marova and G.
